1 - Problems inherent to classic rectifier circuits

In a basic full wave rectifier circuit, two rectifying power diodes are connected to a single load. When a power bridge rectifier is used, the four diodes are mounted in series pairs while only two diodes are conducting current during each half cycle. Rippled waveform obtained at output of these rectifying devices is transformed into a waveform close to DC waveform by the use of input capacitor. Residual voltage ripple waveform can be seen on oscilloscope. Voltage ripple waveform currently shown on all technical papers and books related to rectifying circuit demonstrate clearly that Ohm law is forgotten: only voltage waveform is shown, while current ripple waveform is not taken in consideration.

On a classic bridge rectifier circuit followed by an input smoothing capacitor, figure 1 show on black line the “saw tooth” like aspect of voltage ripple wave that can be seen on oscilloscope. Dotted blue line show waveform of rectified half waves. In red dot line appear the peak charging current Ip and Io, the current available across output load. Note that Io, the average current available across output load is quite low compared to peak charging current.
With a classic bridge rectifier circuit followed by an input smoothing capacitor and referring to figure 1 of last page, it is necessary to take into consideration not only the voltage ripple waveform across output load, but also \( I_p \), the peak charging current and \( I_o \), the output current available across output load. Figure 2 shows A, in yellow, area where charged capacitor current flow into the output load. It is followed by B, area where voltage across capacitor is lower than AC rectified voltage. Result: AC rectified current (lower red line) charge the capacitor while a part of current (around 20%) available across the capacitor flow into the output load. This is why real current available across output load take the shape of red line that can be seen on figure 3. This deformed square of current waveform is an important problem inherent to all conventional full wave and bridge rectifier’s circuits. It cannot be eliminated or minimizes with the help of high speed rectifying diodes, special audio diodes or new generation diodes such as SBD or SiC diodes: even if some improvement is more or less audible, origin of this problem is not treated. It generate strong noise flowing into power supplies and earth lines in devices, while generating noise flowing into AC line.
3 - Problems inherents to classic rectifier circuits

Above mentionned strong current noise explained and detailed on figures 1, 2 and 3, can be seen with a current probe connected to an oscilloscope. **Figure 4** show that during a lag time close to 2 ms, a hole of current appear, meaning that needed current cannot flow into output load during this period.

In audio filed, when such kind of current noise is generated by power supply, there is no way to remove it by conventional methods: IEC filter insertion between AC line and power transformer primary winding, high quality capacitors mounted in parallel on chemical capacitors, use of regulated power supply circuits. The reason is the loose of silent earth and silent power supply lines taken as reference for these circuits. When this kind of noise polluted power supply is used in audio circuit, sound reproduction of small music harmonics is masked by a noise present in power supplies, DC lines and mostly in earth lines, even when regulated power supplies are used. **Figure 5** show a series of music harmonics masked, below 400 Hz, by power supply and earth lines noise. Presence of such kind of noise is degrading sound quality of reproduced audio signals: deepness, music harmonics richness, sound analysis, transparency.

---

**Figure 4**

With conventional rectifier circuit, during a lag time of 2 ms, a hole of current appears and cannot flow into the output load.

**Figure 5**

Harmonic content of classic rectifier power supply connected to a power amplifier receiving above mentionned 100 Hz sawtooth signal. First order and higher order harmonics are masked by noise.

*After Mr Degawa Saburo AES conference, Tokyo 2007*
4 - An important noise problem due to classic rectifier circuits

Noise feedback effect in conventional power supply

Conventional power supply are affected by several noise problems that are degrading the sound quality of audio devices. They cannot be eliminated later on, even with the help of best quality filtering capacitors, EMI shielded filters, chokes or insertion of discrete performant regulated power supply. The reason is because the hole of current seen on figure 4, produce not only a limited current possibility available across output load. It generate a clipped sine wave, a current pulsed noise flowing back to power transformer via secondary winding through negative return circuit. This noise feedback effect is shown on Figure 6. Because power transformer is not designed to support such kinds of high frequencies switching noise, a noise polluted AC waveform appear on power transformer primary winding, not before but after EMI filter that cannot work correctly. Capacitive effect of screen foil present on power transformer transmit noise to core mounted on device chassis. This generate a strong noise pollution of earth line used as electric reference for audio devices such as audio preamplifiers or power amplifier. Above mentionned figure 5 show the increase of noise resulting of this auto-pollution effect.
A short introduction of Mr Degawa

Graduated at Tokai University in 1961, Saburo Degawa joined International Rectifier Japan in 1961. He offered during more than 40 years his best skills to this company, particularly his favorite hobby: high fidelity improvements in audio technology. He worked in this company as a key engineer. He is the author of several invention patents related to audio diodes, special SBD diodes, unique noiseless circuitry for audio use.

One of his most important works is the publication of a white paper (figure 7) at Audio Engineering Society, in 2007, a white paper related to a revolutionary development of series power supply module eliminating noise problems above mentionned. Thanks to this new circuit, hole of current detailed on figure 4 is filled, leading to a dramatic noise reduction. In comparison with a conventional rectifier circuit, ripple reduction improvement can reach 46%. This is due to the filling of current hole of current, thanks to the use of special components matched with time delay circuit including coils. In 2003, he founded A & R Lab, a company dedicated to high end audio devices. He developed then for A&R Lab a wide range of modules for applications in audio and also for cars batteries.
A matchless improvement in power supplies domain

As explained in previous pages, conventional power supply are affected by different noise problems that are inherent to conventional rectifying circuit. They cannot be eliminated later on, even with the use of best quality filtering capacitors, EMI shielded filters, chokes or insertion of discrete performant regulated power supply.

Thanks to Degawa New generation power rectifying module, hole of current above mentionned and seen on figure 4 is completely filled, leading to a very large improvement of current available across output load. This unique possibility is seen on figure 8.

A spectrum analyser show in comparison of figure 5 a complete recovery of harmonic content of a music signal that was previously masked by switching noise generated by conventional power supply. This very significative improvement is show on figure 9. Sound quality, transparency, sound resolution, tridimensional effect, bass definition and articulation, dynamic range covering all the audio range.
A wide range of ultra-performant modules for audio

In the 90’s perfectionist in audio were looking for best audio parts to get the best of their circuit possibilities. They had at their disposal only a limited range of components to improve their power supply circuits, such as FRD (Fast Recovery Diodes) and later some kinds of SBD diodes (Schottky Barrier Diodes) designed for audio application. Even if such kinds of expensives parts can offer some improvement of sound quality, there is nothing to compare face to stunning performances offered by Degawa New Generation rectifying modules and associated LCM and CPM modules.

Degawa New Generation rectifying modules are available in different forms, for applications from low voltage, low current (solid state circuits), low voltage high current (tube heater circuits, solid state circuits until high voltage / low current and medium current circuits (tubes preamplifiers and amplifiers). LCM modules (Line Control Module) and CPM modules (Capacitor Potential Module) complete Degawa New Generation Rectifying Modules, offering incredible improvement of sound performances, far beyond a “just noticiable difference” heard in many cases.

Some Degawa’s invention patents references:

N° 412 6357

New generation of rectifier circuits, LCM, Line Control Module, CPM, Capacitance Potential Module, Special modules for exciting coils of electrodynamic loudspeakers, Cell Exert modules for cars batteries.
Degawa New Generation rectifier’s modules,
Half Wave, 12A series,
Peak forward current 12 Amps,
Peak reverse voltage from 10 V to 1,300 V

These Degawa New Generation rectifying modules are offering stunning, unbeatable advantages based on patented devices using Degawa exclusive components. Conventional rectifying process are inducing, two times each cycle, a hole of current (about 1 ms duration) generated by staircase current accidents between capacitor and rectifying diode current flowing into output load. Degawa New generation rectifier modules offers unique advantage of reducing considerably ripple waveform (around 50% improvement in push-pull mode). Very significative reduction of noise, normally present in DC supply and earth lines, including those using regulated circuit, permit to recover around 10% of sound informations masked by conventional power supplies. Results are unbeatable advantages regarding sound transparency, music instruments harmonics original richness, three dimensional reproduction, S/N ratio, dynamic range, sound realism accuracy.

Degawa New Generation LCM + CPM modules.

Two complementary modules designed to get the best possibilities offered by Degawa New Generation rectifier’s modules.

LCM, series connection Line Control Module and CPM, parallel connection Capacitor Potential Module are two devices that are designed to offer by their mutual benefits the best of stunning possibilities permitted by Degawa New Generation rectifier’s modules. Both modules designed for DC use are offering multiples benefits that are impossible to get with the use of classic RC Pi filtering, LC Pi filtering, use of bypass capacitors, of complementary RC Pi filtering or use of simple of sophisticated regulated or stabilized power supplies. These devices protected by several invention patents such as Japan patent N°3133340 are offering the unique synergy of very efficient noise reduction, not only the residual noise resulting of rectifying process but also the voltage and current noise auto-generated by active circuits such as audio amplifier power stage, driver stage, line stage solicitated by audio signals, transmitting back current back current dynamic noise pollution on ± DC lines and especially earth lines. A wide range of LCM and CPM modules is designed for each audio application, from transistors circuit until high voltage use for tube audio circuits.

Noise spectrum Fourier analysis comparison on rectified power supply using classic bridge rectifier circuit followed by Pi RC filtering (red dotted line) and same circuit using series connected LCM Line Control Module (green plain line). The green plain line show that LCM module reduces and smooth even and odd harmonics residuals of AC rectified half waves. This cannot be obtained with the same efficiency with other circuits or components, including with bypass capacitors or choke filtering.
**Degawa New Generation CPM modules.**

A patented dynamic noise reduction module without equivalent, dedicated to DC power supplies circuits.

CPM Capacitor Potential Modules are patented modules (Japan invention patent N° 3133340) designed to remove static and dynamic noise present in audio power supplies circuits DC supply line and present especially in current form in earth lines. Audio amplifiers power stages, driver stages, line stage and preamplifiers stages sollicitated by audio signals are generating reflected voltage and current fluctuations that are flowing back into DC power supplies. DC power supply lines located close to output stage of audio power amplifiers are strongly concerned by effects like back EMF from loudspeakers. This effect clearly visible in form of voltage modulated noise is also flowing back in current form through filtering capacitor to earth line used as electric reference for audio circuits. This phenomenon explains why classic filtering circuit, bypass capacitors, choke filtering, regulated and stabilized power supply circuits and even diodes or SBD classic diodes are unable to resolve these auto-pollution effects. A wide range of Degawa CPM modules is proposed for most audio circuits, for transistors of tubes applications.

An exemple of symmetrical power supply with center tap on secondary winding using Degawa New Generation modules with:
- Full wave, center tap **New Generation rectifier module** completed by Cx capacitor and C filtering capacitor,
- **LCM Line Control Module**, series connected module dedicated to DC circuits, respecting Input and Output connections,
- **CPM Capacitor Potential Module**, parallel connected, wired close to audio circuit where voltage and current fluctuation are important (for instance power amplifier output stage power supply points).

\[ Cx \text{ value} = C \times 1, 9 \text{ to } 2 \]

For \( C = 100 \, \mu F \), \( Cx = 190 \text{ to } 200 \, \mu F \)

A showroom with instant test comparisons possibilities

At A&R Lab showroom located in Hadano, a city located at about 70 km south-west of Tokyo, the showroom offers the unique possibility of instant A-B comparisons between several original classic and high end audio products and upgraded versions. On most products A-B switches are permitting to listen on the same products, the same music content, at the same sound level how important is the sound improvement obtained when Degawa New generation modules are used. On several high end audio products, including very expensives ones, it is also possible to verify how important is the sound improvement just when CPM modules only are used for upgrading performances.
Degawa New Generation MF modules.
A patented modules designed for power supply of electromagnetic loudspeakers field coils

Thanks to Degawa MF modules especially designed for power supplies of electromagnetic loudspeakers field coils, incredible sound quality improvement can be obtained by simple insertion of patented MF modules (Japan invention patent N°3126184). Degawa’s MF modules are using not only exclusive patented circuits, but also patented components not available in the market in other forms are offering to old field coils loudspeakers from companies such as Western Electric, Jensen Klangfilm or Siemens. Thanks to this MF modules, a very important Eddy current reduction in the magnetic circuit result to a strong reduction of Back EMF effect into last stages of power amplifiers, to power supply lines. Very impressing sound quality improvements obtained concerns sound transparency, gain in dynamic range, low frequencies articulation, subjective bandwidth, sound definition at low levels, and three dimensional stage transcription.

These four legs MF modules (± input, ± output) are designed for different models of electromagnetic loudspeakers using exciting coils connected to voltages from 10 V to 320 V. The MF modules are subject to special order.

MF modules versions:
MF-S: 30 A / DC max 30 V
MF-2: 60 A / DC max 30 V
MF-3: 30 A / DC max 320 V
MF-4: 60 A / DC max 100 V
MF-5: 60 A / DC max 150 V

All MF modules must be connected as close as possible to electromagnetic loudspeakers exciting coils connections.

## New Generation CPM & LCM modules Price-List

### New Generation CPM modules.

**CPM parallel modules for tube amplifiers:**
- CP-1045H, max 450 V  ¥ 4,000
- CP-1045HC, max 450 V  ¥ 4,300
- CP-1050HCsp, DC max 500 V  ¥ 4,800
- CP-1060Hsp, max 600 V  ¥ 4,500
- CP-2045Hsp, max 450 V  ¥ 4,400
- CP-2045HCsp, max 450 V  ¥ 4,800
- CP-2050HCsp, max 500 V  ¥ 5,400
- CP-2060Hsp, max 600 V  ¥ 5,000
- CP-3030Hsp, max 300 V  ¥ 3,700
- CP-3045Hsp, max 450 V  ¥ 4,700
- CP-3060Hsp, max 600 V  ¥ 6,300

**CPM parallel modules for tube amplifiers heater circuits and for tubes and transistors circuits:**
- CP-0205H10M, max 50 V  ¥ 3,200
- CP-0245HC, max 450 V  ¥ 3,000
- CP-0250HC, max 500 V  ¥ 3,200
- CP-0310HC, max 100 V  ¥ 3,000
- CP-1022HC, max 150 V  ¥ 3,200
- CP-3006HC, max 60 V  ¥ 3,200
- CP3010HC, max 100 V  ¥ 3,500
- CP-3015HC, max 150 V  ¥ 3,600

### Degawa New Generation LCM modules.

**LCM series modules for tube amplifiers:**
- LC-2045Hsp, max 450 V  ¥ 4,400
- LC-2060Hsp, max 600 V  ¥ 5,000
- LC-3020Hsp, max 200 V  ¥ 3,700
- LC-3050Hsp, max 500 V  ¥ 5,000
- LC-3060Hsp, max 600 V  ¥ 6,300

For DC Bias circuit:
- LC-1060Hsp, max 600 V bias only  ¥ 4,800

**LCM series modules for low voltages, mainly transistors circuits:**
- LC-3003H, max 30 V  ¥ 2,800
- LC-3006H, max 60 V  ¥ 2,800
- LC-6003Hsp, max 30 V  ¥ 5,400
- LC-6006Hsp, max 60 V  ¥ 5,400
- LC-6015Hsp, max 150 V  ¥ 5,400

Degawa Cell Exert Module CE-1503H Ver II
A revolutionary module using patented semiconductor, patented circuit (Japan N° 31828714) designed to improve car’s performances.

Thanks to the use of last generation technologies in domain of semiconductors, this module is using patented circuit and patented semiconductors especially designed of electronic circuit of cars. With this Version II, a simple and fast connection (5 mn only) of this module across battery improve considerably performances of circuits taking in charge engine electric control.

1 – Motor-fuel consumption reduced from 10 to 15 %.
2 – Suppression of reverse pulsed current into earth line electric circuit improving battery lifetime.
3 – Strong reduction of pulsed noise in electric circuit improve sound quality of car’s radio and CD device.
4 – Better acceleration feeling of engine.
5 – Audible reduction of engine noise.

These stunning improvement possibilities cannot be obtained without the use of dedicated Degawa patented semiconductors. Offer benefits of ultra low conducting resistance, very high pulsed current possibilities, and very high voltage isolation protecting this device against static electricity effects noted on cars.

CE-1503H Ver 2, 12 volts version ¥17,400-
CE-21003H Ver 2, 12 volts version ¥29,000-
